

## Photosynthesis & Environment

how can we measure photosynthesis?

- measure amount of glucose produced
- measure amount of CO<sub>2</sub> consumed
- measure amount of O<sub>2</sub> given off

## Rate of Photosynthesis

how fast does photosynthesis proceed?

amount CO<sub>2</sub> consumed in period of time

## 4 Factors affecting rate of photosynthesis

- 1-light intensity
- 2-temperature
- 3-concentration of CO<sub>2</sub>
- 4-concentration of O<sub>2</sub>

## Light intensity

what does graph say about light intensity?

as light intensity increases, photosynthesis increases up to a point, then it begins to decrease

before we reach intensity of full sunlight, photosynthesis has reached saturation point & the rate levels off

light rx become saturated w/sunlight E & they proceed as fast as they can

in still brighter light, chlorophyll

accumulates E faster than it can be used in ETS, so some E goes to O<sub>2</sub>

molecule & makes H<sub>2</sub>O<sub>2</sub> (H peroxide)

this damages chloroplasts, decreasing the rate of photosynthesis

this is called photoinhibition

## Effect of temperature on rate of photosynthesis

- what does this graph say?

graph shows there is an optimum temp

range 15 C - 30 C

above & below these temp, photosyn is inhibited -----Why?

what is limiting condition?

H<sub>2</sub>O

too cold, H<sub>2</sub>O moves too slow, frozen

too hot, H<sub>2</sub>O evaporates

## Effect of CO<sub>2</sub> concentration

what does graph say?

as the CO<sub>2</sub> concentration increases, the rate of photosynthesis increases up to a point, but then levels off

above CO<sub>2</sub> saturation point, an increase in CO<sub>2</sub> has no more effect

light, temp, CO<sub>2</sub> all affect rate of photosyn at same time  
factor in shortest supply is limiting factor  
if you have optimum temp, optimum CO<sub>2</sub> levels, but low light, then light is limiting factor

Concentration of O<sub>2</sub> in atmosphere

what does this graph say?

at low levels of O<sub>2</sub>, photosyn works great  
the process of photosynthesis evolved in an atmosphere of methane gases, H<sub>2</sub>, but not O<sub>2</sub>

as more and more plants photosynthesized, amount of O<sub>2</sub> in atmosphere increased

today, O<sub>2</sub> concentration is 20%

above 20%, photosynthesis is inhibited

why? enzyme rubisco fixes CO<sub>2</sub> to RuBP  
and the enzyme can get confused btw CO<sub>2</sub> & O<sub>2</sub> due to its structural formula

structural formula of CO<sub>2</sub>:  $O=C=O$

structural formula of O<sub>2</sub>:  $O=O$

both molecules are held together by double bonds that are similar distance apart  
so they both fit into the active site of rubisco

But if atmospheric O<sub>2</sub> is 20%, how can it get higher?

CO<sub>2</sub> is brought into plant cells by pores in leaves called stomates

O<sub>2</sub>, produced during photosyn leaves plant cells by stomates

H<sub>2</sub>O is brought into plant cells by roots, but if it is hot, H<sub>2</sub>O can also leave plant cells by stomates, called transpiration  
these pores can be opened & closed by plant cells as needed

if stomates close to prevent H<sub>2</sub>O loss,  
CO<sub>2</sub> can't get in and O<sub>2</sub> can't get out  
thus, CO<sub>2</sub> levels drop and O<sub>2</sub> levels rise

when CO<sub>2</sub> is fixed by RuBP--->forms 2 PGA  
when O<sub>2</sub> is fixed instead---->forms 1 PGA &  
1 molecule glycolate (2C)  
glycolate is taken out of chloroplast---->  
broken down to CO<sub>2</sub>, thus we lose some C  
called photorespiration

thus, relatively high levels CO<sub>2</sub>---->increases  
photosynthesis  
but relatively high levels O<sub>2</sub>----->decreases  
photosynthesis and increases  
photorespiration

diff groupings of plants based on photosyn

majority of plants are C3 plants

these do photosyn as we have learned

called C3 b/c when CO<sub>2</sub> is fixed by RuBP, it

makes PGA, a 3 C compd

C4 plants & CAM plants have evolved adaptat  
to hot, environments

C4 plants: sugarcane, corn, crabgrass

where they grow H<sub>2</sub>O is available, but high  
temps make plants lose H<sub>2</sub>O

so they fix CO<sub>2</sub> by combining with 3C acid,  
thus making a 4 C compd (C4 plant)

this combining of CO<sub>2</sub> w/3 C acid makes  
another step in pathway (this is also in diff  
cell) and this step uses a diff enzyme,  
so it does not get confused btw O<sub>2</sub> & CO<sub>2</sub>

then 4C compd is transported to Calvin cycle  
where it releases CO<sub>2</sub> & cycle proceeds

so C4 plants can close stomates to prevent  
H<sub>2</sub>O loss, but store CO<sub>2</sub> by combining w/  
3C acid, then there is lots of CO<sub>2</sub> available  
for rubisco, so it fixes CO<sub>2</sub> instead of extra  
O<sub>2</sub> that is also present

these plants are very efficient & grow well  
even better than other crop plants (soy,  
rice, wheat)

CAM plants: crassulacean acid metabolism  
also adapted to hot, dry environments, deserts  
these plants open stomates at night, fix CO<sub>2</sub>  
into acids  
stomates close during day to conserve H<sub>2</sub>O  
acids release CO<sub>2</sub> & it enters Calvin cycle  
this is not efficient process  
slow growth

## Photosynthesis & Atmosphere

photosynthesis is the largest single  
biochemical process on earth  
produces 90 billion metric tons O<sub>2</sub> & organic matter  
uses 140 billion metric tons CO<sub>2</sub>, 110 billion metric  
tons H<sub>2</sub>O

so why is CO<sub>2</sub> content of atmosphere increasing?  
people burning fossil fuels for energy  
burning rainforests  
less trees removes less CO<sub>2</sub> from  
atmosphere

so what is the effect?

how does increasing CO<sub>2</sub> directly affect  
plants & photosynthesis?

CO<sub>2</sub> is increasing temperature of earth  
how does this affect photosynthesis?
